## Crazy Choices Game Tally Table

| Name of <br> player: | \# of <br> favorable <br> outcomes: | Total \# of <br> outcomes: | Total \# of <br> games <br> played: | \# of <br> games <br> won: | Experimental <br> probability*: |
| :--- | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  |  |
|  |  |  |  |  |  |
|  |  |  |  |  |  |
|  |  |  |  |  |  |
|  |  |  |  |  |  |

* The following formula should be used for experimental probability:

Experimental probability = (\# of games won $) /($ Total games played $)$
Obviously, experimental probability is computed after all the data is collected. Here is the example of the game statistics. Anton played with a spinner that had 3 equal sections and won if the spinner stopped at Section 1 or 2, Bella played with a ten-sided die and won if the die rolled $2,4,6$ or 8 up, and Cindy played with a coin and won if it fell heads up. Students planned to play fifty games. They tallied the results of every game and then counted their victories:

| Name of <br> player: | \# of <br> favorable <br> outcomes: | Out of the <br> total of this <br> many <br> outcomes: | Total <br> number of <br> games <br> played: | Number of <br> games won: | Experiment <br> al <br> probability*: |
| :---: | :---: | :---: | :---: | :---: | :---: |

The players concluded that Anton had the best chances of winning, followed by Cindy and then Bella.
